

## Lab #3 - Assessment Worksheet

### Enabling Windows Active Directory and User Access Controls

---

**Course Name and Number:**

202170 CYBS-5F70-7QA

---

**Student Name:**

Christopher Phan

---

**Instructor Name:**

Karen Winters

---

**Lab Due Date:**

09/14/2021

---

### *Lab Assessment Questions & Answers*

---

1. What are the three fundamental elements of an effective security program for information systems?

Confidentiality, Integrity, and Availability.

2. Of these three fundamental controls, which two are used by the Domain User Admin to create users and assign rights to resources?

Confidentiality and integrity are the main two elements that administrators have control over and are able to choose selective rights.

3. If you can browse a file on a Windows network share, but are not able to copy it or modify it, what type of access controls and permissions are probably configured?

List folder contents

4. What is the mechanism on a Windows server where you can administer granular policies and permissions on a Windows network using role-based access?

Windows Group Policy

5. What is two-factor authentication, and why is it an effective access control technique?

Two factor authentication involves a two step process, where the user has to input something that they already know, such as a password, and then it involves either something that a person already has beyond technology OR something that a person owns and is made to unlock something.

6. Relate how Windows Server Active Directory and the configuration of access controls achieve CIA for departmental LANs, departmental folders, and data.

The Windows Server Active Directory achieve the three elements of CIA (Confidentiality, Integrity, and Availability), by admins able to choose which LANS, folders, and data are available for any users on the network, choosing their set privileges, and ability to setup privacy and password policies. With this directory, the administrator can restrict the information to only those who are allowed to view said information and who can tweak it. As well as choose which users are able to keep the information as secure and accurate as possible, to be the best usage of data. Lastly, the directory allows all data to be available to users who are authorized, and is able to keep all data easily accessible for those that are permitted, but protects from intruders. With this, the local networks, folders, and data that go to their respected departments are only accessed by authorized users only.

7. Is it a good practice to include the account or user name in the password? Why or why not?

No, it is not a good idea whatsoever to include the user name or account in a password, as it makes the password that much more vulnerable and easily decoded, since it is possible to easily guess the password due to the user name or account publicly known. Passwords are not meant to be easily known nor known by more than one person, thus making one's password easier to decode puts a person's information at risk, as well as their peers and business possibly.
